Q: How to extract substring from a string in Python? string = "I like '>hot weather'. string2 = "I like '>sky'. string3 = "I like '>fish'. string4 = "I like '>crocs'. string5 = "I like '>Banks'. I want to extract the substring '>' to a list, l = ['sky', 'fish', 'crocs', 'Banks'] A: import re re.findall("'.*?>',',.*?>','.*?>',',.*?>',',.*?>',',',',',.*?>',',',',.*?'" should help you. The background description provided herein is for the purpose of generally presenting the context of the disclosure. Work of the presently named inventors, to the extent it is described in this background section, as well as aspects of the description that may not otherwise qualify as prior art at the time of filing, are neither expressly nor impliedly admitted as prior art against the present disclosure. Modern electronic devices can be complex, combining several electronic components and/or subsystems. A particular example is a cellular telephone, which can include a radio, speaker, microphone, display screen and a variety of other features. For a variety of reasons, an electronic device is often designed to include a memory to store data, such as information related to the use and operation of the device. This is particularly true of electronic devices that are constantly connected to a network, such as cellular telephones. In such cases, memory is generally a cost-effective way of storing data, as the electronic device is designed to operate even in the absence of a network connection. An electronic device may utilize a non-volatile memory to store data in the electronic device. A non-volatile memory allows data to be retained in the absence of an external power source. A popular non-volatile memory is a FLASH memory. A

Report of the Calculus 12th International Conference: Varieties and Tools in the Calculus (Conference in Logic, Model Theory, Mathematics and Computer Science, July 21st-25th 2015, Freiburg, Germany) Category: Conference Papers; ISSN: 2217-2623 (Print), 1377-2424 (Online) Abstract. In this article we report on some work done at the 12th international conference on Varieties and Tools in the Calculus. Abstract: A key argument in the literature against Calculus-based proof assistant programs is that they can be usefully applied only to "trivial" cases. The idea is that whenever the statements to be proved are "obviously true" (or true in some other intuitive sense), then that is enough to give a proof. However, the idea that triviality is the distinguishing feature of the trivial is a belief or understanding about the nature of truth, not a property of the calculus. As a result, a calculus is not defined in terms of whether theorems are trivial or nontrivial. So when a program claims to be able to prove theorems which are obviously true, but cannot actually do that, the argument against the program is beside the point. Here we suggest a way to define triviality of theorems, and show how this allows a calculus to prove theorems which are obviously true. Part III Ordinary Differential Equations 9.
