Relationship between quality of life and the level of independence in elderly patients with dementia. The quality of life of elderly demented patients may be influenced by the disease-related severity of cognitive decline. However, there is little information concerning the relationship between the level of independence and quality of life in this population. The current study compares the quality of life of elderly patients with dementia who were more or less dependent on daily living activities and explores the factors associated with quality of life. A total of 105 demented patients from the outpatient clinic of the Geriatric Mental Health Unit were included. Dependency in daily living activities was assessed using the Activities of Daily Living Scale. Quality of life was assessed using the Geriatric Depression Scale, Mini-Mental State Examination, and SF-36. Patients with dementia and a higher level of independence scored higher on the SF-36 mental health component than those with a lower level of independence. The duration of cognitive decline, the presence of delusions, and the level of depression were all associated with the quality of life of the demented patients. The quality of life of elderly demented patients is influenced by their level of independence. These findings may have implications for the provision of care for these patients.

Evidence of a new lectin-like protein in the flagella of *Strongyloides stercoralis*. In the helminth *Strongyloides stercoralis*, the flagella could be extracted from the parasites by treatment with 0.5 M NaCl and 1 mM EDTA. In order to determine the nature of the protein(s) present in the flagella, the detergent-soluble fraction from intact flagella was separated by electrophoresis. The analysis revealed three polypeptides with apparent molecular masses of 50, 100, and 230 kDa. The flagella showed a strong and specific binding to concanavalin A-Sepharose which was not blocked by treatment with 1 mM
