The study reveals the role that about 10 percent of the world's population plays in the spread of infectious diseases. The study focused on China, where the number of people infected with COVID-19 grew exponentially during the period studied, from mid-December 2019 to early January 2020. The researchers found that local networks of humans were crucial in the rapid spread of the disease. Those networks evolved to become denser and more resilient, as the disease spread through the population. Although COVID-19 is still spreading, the recent discovery of cases in new places and new people indicates that transmission does not have to be exponential in order for the disease to reach a large proportion of the world's population. "It's not just the case that the disease is spreading fast and reaching a lot of people, but that local transmission networks are becoming denser and more robust," said study author Michael Turell, an assistant professor of medicine at the Bloomberg School. "In the absence of intervention, the virus can grow exponentially. But with intervention, there is a natural slowing of that process. The critical question is, can we halt transmission?" In analyzing population data from Wuhan, China, where COVID-19 started, Turell and his colleagues found that the majority of transmissions (90 percent) came from local networks of people. When the population is connected to each other by these networks, the virus can travel from person to person much more easily. However, after the disease is imported to a new community, it grows exponentially in the

population and ultimately kills people. “There are two ways of thinking about the spread of infectious diseases: spread per unit time

Aug 30, 2018 Deepstatus.exe is a powerful anti-virus software that can help you to remove all types of virus. It is able to detect and remove a lot of threats on the computer.
