Screenshot: Please click the "HELP" icon.Determination of the concentration of formic acid in aqueous samples by capillary electrophoresis in the presence of an inhibitor using a dual thin-layer electroosmotic flow ($\sim$0.06 cm(2) V(-1) s(-1)) and dual electrostatic transport. A capillary electrophoresis (CE) method was developed for the determination of formic acid in aqueous samples. Formic acid is a widely used preservative that is involved in fish spoilage. The determination of formic acid in aqueous samples is difficult due to the rapid conversion of the acid to formic acid methyl ester. However, the potential of formic acid is still used in the food industry. Therefore, a CE method to determine the formic acid concentration in aqueous samples was developed to enable us to identify possible food contamination. The developed CE method was successfully applied for the determination of the concentration of formic acid in aqueous samples, and the obtained results were compared with an HPLC method. At pH 2.2, the determination of 10 μmol L(-1) formic acid was conducted by applying a dual thin-layer electroosmotic flow ($\sim$0.06 cm(2) V(-1) s(-1)) in the CE method. At pH 3.0, a dual electrostatic transport system ($\sim$0.36 cm(2) V(-1) s(-1)) was used instead of the

electroosmotic flow. Under these conditions, well-defined peaks for formic acid were obtained within a 15-s analysis time. By optimizing the conditions,

Minimum: OS: Windows 7/8/10/Windows Server 2003 Processor: Intel Core 2 Duo E6550, AMD Phenom II X4 940 Memory: 3 GB RAM Graphics: nVidia GTS 450 DirectX: Version 9.0 Recommended: Processor: Intel Core 2 Duo E6600, AMD Phenom II X4 970 Memory: 4 GB RAM Graphics: nVidia GTS
