[Usefulness of Holter electrocardiography in the long-term follow-up of patients with coronary arterial disease]. Holter electrocardiography is an important technique in the management of patients with coronary arterial disease. It is useful for detecting asymptomatic myocardial ischemia, risk stratification and prediction of cardiac events during the follow-up of patients with coronary arterial disease. Myocardial ischemia is the most important risk factor for the development of unstable angina and myocardial infarction during the follow-up of patients with coronary arterial disease. The technique is useful for predicting late cardiac events such as ventricular arrhythmia, pericarditis, and sudden cardiac death in patients with coronary arterial disease. The prognostic value of Holter electrocardiography is greater when it is recorded during daily activities than during exercise. The best timing for Holter electrocardiography is the recording of 24-hour Holter electrocardiography. Accurately monitoring the patient's daily activities over a 24-hour period is useful for detecting asymptomatic myocardial ischemia. It is especially important in patients with atypical chest pain or exercise-related symptoms. The technique is useful for predicting the risk of ventricular arrhythmias, pericarditis, and sudden cardiac death. The prognostic value of Holter electrocardiography is greater in patients without previous myocardial infarction than in patients with previous myocardial infarction or those with normal coronary arteriography. e s t i n t e g e r $?$ 3 W h a t i s 6 3 8 9 t o t h e p o w e r o f 1 $/$ 9 , t o t h e n e a r e s t i n t e g e r $?$ 3 W h a t i s t h e s q u a r e
